Tiki Calculations started out as an advanced rating system, and has since evolved into a powerful general purpose calculations system.

Advanced Ratings & Calculation Syntax

Overview

Use this page to configure a "rating" system to evaluate tracker items or wiki pages. Introduced in Tiki5, the advanced rating feature allows for more control over the aggregation of scores. You will also see in this documentation page how to use the calculations syntax, which also applies at the Mathematical Calculation Tracker Field.

To access

Click the Ratings icon on the Admin Panel or Access http://example.org/tiki-admin.php?page=rating

Note

Tiki currently supports sorting through advanced rating in:

- Articles
- Wiki
- Comments
- See also Mathematical Calculation Tracker Field

<table>

| Rating recalculation mode: | Determines when and how rating aggregates are recalculated:  
  * **On vote** (default): indicates that the score for the object should be recalculated every time a vote is performed. This option is suitable for sites with lower volumes and relatively simple calculation methods when ratings are used.  
  * **Random on load**: will cause a few scores to be calculated on page load on a random basis (odds and count can be configured to adapt to site load). This option is suitable for calculation rules involving time that must be recalculated even if no new votes occurred.  
  * **Random on vote** is similar to random on load, but will recalculate multiple scores (not necessarily including the current object) when a vote is performed. It is suitable for similar situations. The best option will depend on site load.  
  * **Periodic**: is the best option for heavy load sites, making sure all calculations are done outside the web requests. A cron job must be set-up manually by the site's administrator. A sample script is available at the end of this page.  
  Depending on the site load, some options may be better than others; on large volume sites, we recommend **cron job**. The **Recalculate on vote** recalculation may be inaccurate if rating calculation depends time.  
  **Before any attempt to re-index the object:** Ties into the Search and List from Unified Index and updates the calculation at index-time. | Recalculate on vote |
| Recalculation odds (1 in X): | | |
| Recalculation count: | | |

**Wiki**

<table>

**Articles**

<table>
<thead>
<tr>
<th>Enable a simple rating bar at the top of each articles page.</th>
</tr>
</thead>
<tbody>
<tr>
<td>User ratings on articles</td>
</tr>
<tr>
<td>Article rating options:</td>
</tr>
</tbody>
</table>

The feature must first be enabled through this same administration panel. Along with the feature, a few options are available. Among them, the score recalculation period must be defined. These are the available options:
• **On vote (default)** indicates that the score for the object should be recalculated every time a vote is performed. This option is suitable for sites with lower volumes and relatively simple calculation methods when ratings are used.

• **Random on load** will cause a few scores to be calculated on page load on a random basis (odds and count can be configured to adapt to site load). This option is suitable for calculation rules involving time that must be recalculated even if no new votes occurred.

• **Random on vote** is similar to random on load, but will recalculate multiple scores (not necessarily including the current object) when a vote is performed. It is suitable for similar situations. The best option will depend on site load.

• **Periodic** is the best option for heavy load sites, making sure all calculations are done outside the web requests. A cron job must be set up manually by the site's administrator. A sample script is available at the end of this page.

For the random options, the odds of recalculating must be specified as a dice roll. For each occurrence of a recalculation, a limit to how many scores can be calculated must be specified to avoid the hang-up effect on the page load.

The value ranges for each object type can also be specified through the administration panels.

The common *sort_mode* parameter to lists can be used to activate sorting using advanced ratings. To do so, the sort mode must be set to *adv_rating_X_asc* or *adv_rating_X_desc* where *X* is the ID of the rating configuration. The default sort can also be set to advanced ratings in the administration panel where applicable.

### Calculation configuration

From the administration panel, new calculations can be added. Initially, only the name is required. When created, the calculation will contain suitable default values.

For wiki pages:

Thus, visitors can provide feedback like:

• Did this page help you solve the issue?
• Was this page easy to understand?

### Sorting items according to advanced rating

Note that the sort mode to use when needing to sort by advanced rating is either *adv_rating_xx_asc* or *adv_rating_xx_desc*, where *xx* is the ratingConfigId.
Set-up

By default, each calculated value is kept for 1 hour (3600 seconds). This limit does not apply when recalculating on vote, but is used for every other technique to avoid recalculating the same scores over and over again.

The calculation is defined as a small piece of code, similar to functional languages, which is very close to mathematical representations. Creating custom formulas is expected to require some mathematical skills. However, this documentation should provide examples for most frequent cases.

The editor in the administration panel performs extensive validation and will make it impossible to save the formula unless it can be evaluated. Checks are performed for:

- Syntax errors
- Unknown functions
- Missing arguments
- Invalid argument values
- Unknown input variables

**Default formula**

```
(rating-average (object type object-id))
```

It can be altered to limit the vote consideration to a limited time span, 30 days for example.

**Recent votes only**

```
(rating-average
 (object type object-id)
 (range (mul 3600 24 30)))
```

In the language, spaces do not matter. Only the parenthesis indicate structure. `rating-average` is a function that fetches the ratings for a given object. `type` and `object-id` are standard variables fed when calculating a rating. `object` and `range` are configuration options of the function.

`mul` is a mathematical function. `(mul 3600 24 30)` is equivalent to `3600*24*30`.

The functions can be combined in various ways. For example, we could calculate a score that considers the votes from the past month, but gives extra emphasis on the recent ones.

**Combined vote duration**

```
(add
 (rating-average
  (object type object-id)
  (range (mul 3600 24 30)))
 (rating-average
  (object type object-id)
  (range (mul 3600 24 7)))
```
Even though the votes are 1-5, the final score can be on an entirely different scale. The language is also extensible if the calculation needs to be combined with other factors or weight. See Rating Language.

All available options are documented in the following section.

Syntax

General Reference

Sample and use case

add (Sum)
Performs a simple sum accepting multiple input

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>(add 3 4)</td>
</tr>
<tr>
<td>- &gt; 7</td>
</tr>
<tr>
<td>(add (add 3 4) 5)</td>
</tr>
<tr>
<td>- &gt; 12</td>
</tr>
<tr>
<td>(add 3 4 5)</td>
</tr>
<tr>
<td>- &gt; 12</td>
</tr>
<tr>
<td>(add 4 0.5)</td>
</tr>
<tr>
<td>- &gt; 4.5</td>
</tr>
</tbody>
</table>

sub (Substract)
Performs a simple substraction accepting multiple input

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>(sub 3 4)</td>
</tr>
<tr>
<td>- &gt; -1</td>
</tr>
<tr>
<td>(sub (sub 3 4) 5)</td>
</tr>
<tr>
<td>- &gt; -6</td>
</tr>
<tr>
<td>(sub 3 4 5)</td>
</tr>
<tr>
<td>- &gt; -6</td>
</tr>
<tr>
<td>(sub 4 0.5)</td>
</tr>
<tr>
<td>- &gt; 3.5</td>
</tr>
</tbody>
</table>

div (Divide)
Performs a simple division accepting multiple input values.
mul (Multiply)

Performs a simple multiplication accepting multiple input values.

**Examples**

```
(mul 3 4)  
  -> 12
(mul (mul 3 4) 5)  
  -> 60
(mul 3 4 5)  
  -> 60
(mul 4 0.5)  
  -> 2
```

and / or

**and**

Ensures all elements evaluate to true.

**Examples**

```
(and 3 2 1 2 3)  
  -> 1
(and 2 3 0 2)  
  -> 0
```

**or**

Ensures that at least one element evaluates to true. Elements are evaluated sequentially until a false element is found. Others are left unevaluated.

**Examples**

```
(or 3 2 1 2 3)  
  -> 1
(or 2 3 0 2)  
  -> 1
(or 0 0)  
  -> 0
```
avg
Calculates the average of multiple values. All entries in the list will be flattened if arrays are present.

Examples
(avg 1 2 3)
-> 2
... given list contains [1, 2, 3]
(avg list)
-> 2

Note: Unless told otherwise avg treats empty values and zeros the same, but you can use [if] to check like this:

Empty example
(if (not (equals calcValue_3 ""))
  (avg calcValue_1 calcValue_2 calcValue_3)
  (if (not (equals calcValue_2 ""))
    (avg calcValue_1 calcValue_2)
    (if (not (equals calcValue_1 ""))
      calcValue_1
    )
  )
)

avg can be used together with other fields values as well as an item-list field displaying values from another tracker.

Calculate the average of values from a different tracker in an item-list
The field permanameListofnumbers contains values 1 and 3 (grabbed from tracker permanameNumbersfromanother tracker)
(avg
  (for-each
    (list permanameListofnumbers)
    (formula (concat permanameNumbersfromanother tracker))
  )
)
-> 2

clean
Clean accents and special characters from a string of text, replacing the accented characters with the non-accented equivalent where possible. Added in Tiki 18.2

Examples
(clean (str foó barça caña))
-> "foo barca cana"
coalesce

Returns the first non-empty value from the list.

**Examples**

```plaintext
(coalesce 3 4)  
  -> -3  
(coalesce (sub 3 3) 5)  
  -> 5  
(coalesce 0 0 (str) -10)  
  -> -10  
(coalesce 0 0 0 0)  
  -> 0
```

comment

Any comment block is stripped from the formula at parse-time.

**Examples**

```plaintext
(mul  
  1  
  2  
  (comment Simple enough?))  
  -> 2
```

concat

Concatenates a string of text. (new in Tiki12)

**Note:** The quoted string syntax was included in Tiki13.

**Examples**

```plaintext
(concat  
  (str $)  
  1234  
)  
  -> "$1234"  
(concat 14  
  (str %)  
)  
  -> "14%"  
(concat 14 "%")  
  -> "14%"
```

contains

Searches for a value within a vector of values (new in Tiki15.0, backported to Tiki14.2 and Tiki12.5).

**Examples**

```plaintext```
Note that if you are using an argument value in here, you would need to `eval` and then put brackets around to make it work.

```plaintext
args.values_by_permname.version: 305,306
```

```plaintext
(count 307 (eval(args.values_by_permname.version)))
- 0
(count 305 (eval(args.values_by_permname.version)))
- 1
(count 30 (eval(args.values_by_permname.version)))
- 0
```

**count**

Returns the total number of entries within an array passed as argument.

**Examples**

```plaintext
(count results)
- 5
```

You can use it with `split-list` to count the number of items in a list or in an item-link (should work with item-list dynamic item-list).

**Counting item in item-link**

Let say I have an item-link `permanameBooks` with 12 items linked.

```plaintext
(count
    (split-list
        (content permanameBooks)
        (separator ,)
        (key a)
    )
)
- 12
```

*Only one key need to be created it will populate properly*

**Currency**

*New in Tiki21: https://sourceforge.net/p/tikiwiki/code/71175*

Allows to convert a calculation into currency field. Expects 3 arguments. First is the calculation of the amount. Second is the source currency - i.e. which currency is the amount in? Third is the currency field.

**Examples**
If you use the Canadian daily exchange table from the Bank of Canada you can retrieve sourceCurrency string from currencyFieldPermName (i.e.: FXUSD, CAD) using this formula:

Get the last 3 char of a value in a tracker

(substring currencyFieldPermName -3)

Examples

(currency (cal-of-the-amount) (substring currencyFieldPermName -3) currencyFieldPermName)

currency-convert

New in Tiki22: https://sourceforge.net/p/tikiwiki/code/76059

This adds 2 things:

1. currency-convert math function which will allow us to convert specific math functions to CAD when you need only CAD values.
2. using default tracker for exchange rates when parsing a math function output like 123USD without a currency field context. The tracker must contain 'exchange rate' in its name in order to be found. This will be until we have a proper concept of system trackers.

date

Takes two optional arguments, format and timestamp and uses the PHP date function. See here for reference. Format defaults to "U" which is the Unix timestamp, and the timestamp defaults to "now".

Date Examples

(date)
> Returns "1438358437" currently

(date (str Y-m-d H:i:s))
> Returns "2015-07-31 17:00:43" currently

(date (str r) theTimeAndTheDate)
> Returns "Tue, 16 Jun 2015 09:23:09 +0100" for instance, where theTimeAndTheDate is the permanent name of a tracker field in the same tracker.

equals

Compares multiple values.

Examples
(equals 2 (add 1 1) (sub 4 2))
  -> 1 (equivalent of 2 == 1+1 & 2 == 4-2)
(equals (add 1 1) 3)
  -> 0

for-each
For a list of value pairs, such as the output of split-list, evaluates a formula for each set of values, returns the list of results.

Within the formula, variables coming from the list will be used first. Fallback will be on the other variables available in the execution context.

As of Tiki18, list items can be the output of ItemsList tracker field where individual formula fields are the linked fields from the other tracker. See example below.

Examples

... given items contains [{a: 1, b: 2, c: 3}, {a: 2, b: 3, c: 4}]
(for-each
  (list items)
  (formula (mul a b c)))
-> [6, 24]

... given items contains [{a: 1, b: 2, c: 3}, {a: 2, b: 3, c: 4}]
... and d contains 10
(for-each
  (list items)
  (formula (mul c d)))
-> [30, 40]

... given trackerDetails is an ItemsList field pointing to another tracker with a field detailsAmount
... and particular tracker item has 2 linked items with detailsAmount = 30 and 40
(add
  (for-each
    (list trackerDetails)
    (formula (concat detailsAmount))))
-> 70
This formula sums the detailsAmount column from the other tracker for all items linked from this tracker's item.

hash
Generates a hash based on multiple values. Used primarily to generate aggregate hashes in the PluginActivityStream. Note that because it is a hash, the exact value coming out does not matter. Only that given the same parameter, it will produce the same value.

Examples

(hash 1)
  -> [sha1("1")]
if
Conditionally evaluates a branch.

**Examples**

```
(if (equals 2 2) 42 -1)
-> 42
(if (equals 2 1) 42 -1)
-> -1
```

You can use it with STR to apply a condition on a string within another field.
IE: if permanameFieldName contain "Bernard"

**If used with a string to show another field**

```
(if (equals permanameFieldName (str Bernard)) permanameFieldMoney (str 0))
-> Will output the value of permanameFieldMoney if true (permanameFieldName = Bernard)
-> Will output 0 if this is not true (permanameFieldName ≠ Bernard)
```

**IsEmpty**

*New in Tiki14: https://sourceforge.net/p/tikiwiki/code/53588*

**Examples**

```
(IsEmpty 1)  
-> 0
(IsEmpty 0)  
-> 1
```

You can also use a tracker field permaname as true or false value or as returned value from the tracker item.
Here we combine if, equals and is empty to create a different output for each case else the default output (0 or 1) will be returned.

```
(if (equals 1 (IsEmpty permaname)) (str empty) (str notempty))
  if the field has no value (1) -> empty
  if the field has a value (0) -> notempty
```

IsEmpty may also be used to test if an array is empty.
However in some case you may have an error. coalesce seems to work better for testing and displaying tracker field values.
less / more

less-than

New in Tiki14.1 and Tiki12.5: Checks whether the first value is less than the second.

**Examples**

```plaintext
(less-than 3 (add 2 2))
-> 1
(less-than (add 2 2) 3)
-> 0
```

more-than

New in Tiki14.1 and Tiki12.5: Checks whether the first value is more than the second.

**Examples**

```plaintext
(more-than 3 (add 2 2))
-> 0
(more-than (add 2 2) 3)
-> 1
```

lower

Converts string to lower case.

**Examples**

```plaintext
(lower Foo)
-> foo
```

map

Generates a map (or dictionary).

**Examples**

```plaintext
(map
  (key1 1)
  (key2 2)
  (key3 (str value3))
)
-> {"key1": 1, "key2": 2, "key3": "value3"}
```

Not

New in Tiki14: [https://sourceforge.net/p/tikiwiki/code/53590](https://sourceforge.net/p/tikiwiki/code/53590)

number-format

Format a number with grouped thousands. See PHP's number_format function for exact arguments. New in
Examples

(number-format 123456.78)
  -> "123,456.78"
(number-format 120.334 (str 3))
  -> "120.334"
(number-format 120.334 (str 0))
  -> "120"
(number-format 123456.78 (str 2) (str ,) (str ))
  -> "123 456,78"

pad

*New in Tiki15 committed in r57094*

Takes two to four arguments, input string, output length, padding string (defaults to a space) and padding type (defaults to right)

This example right pads prices in a simple products tracker for sorting and filtering

```
(pad
   productsPrice
   8
   (str 0)
   (str left)
)
```

round

Rounds to a specific number of digits (new in Tiki12)

Examples

(round 4.556234342234 2)
  -> 4.56
(round 4.556234342234)
  -> 5

str

Generates a static string when needed and the processor attempts to process the string as a variable. Any arguments will be concatenated using spaces.

*Note:* The quoted string syntax was included in Tiki13.

Examples

(str hello-world)
  -> "hello-world"
(str hello world)
-> "hello world"
(str
  hello
  world
  foobar)
-> "hello world foobar"
(str (mul 2 3) "= 6")
-> "6 = 6"
(str some text with new line~nl~)
-> "some text with new line\n"

str-to-time
Parse about any English textual datetime description into a Unix timestamp. See PHP's strtotime function for more details on valid formats and options. New in Tiki18.

**Examples**

(str-to-time (str 2017-06-05))
-> "1496610000"
(date (str Y-m-d) (str-to-time (str +1 day) (str 2017-05-29)))
-> "2017-05-30"

**Numbers of days between a date in a field and now**

(round (div (sub (str-to-time permanameDate) (date)) 86400) 0)

str-replace
Replace substring in a string. See PHP's str_replace function for exact arguments. New in Tiki18.

**Examples**

(str-replace (str foo) (str bar) (str hello foo))
-> "hello bar"

preg-replace
Perform a regular expression search and replace on a field value. The preg-replace math function is available in Tiki 21+

**Using preg-replace to return part of a string before a | (pipe)**

The field permanameMonthAndUser contain "June | Bernard"
(preg-replace (str /\|\.*$/) (str ) permanameMonthAndUser)
-> "June"

**Using preg-replace to return part of a string after a | (pipe)**

The field permanameMonthAndUser contain "June | Bernard"
(preg-replace (str /^\.*?\|/) (str ) permanameMonthAndUser)
split-list

Produces a multi-dimensional array out of a text string. Each line is expected to be an independent value, each line will be split by a separator into the specified keys.

**Examples**

```
... given str contains a list of 3 comma-separated values
(split-list
  (content str)
  (separator ,)
  (keys a b c))
-> [{a: 1, b: 2, c: 3}, {a: 2, b: 3, c: 4}]
```

subtotal

Special function to aggregate data in a table. See Report formatting for more details.

upper

Converts string to upper case.

**Examples**

```
(upper Bar)
-> BAR
```

Advanced Rating-specific Reference

**rating-average and rating-sum**

The rating functions calculate the score from the rating history table. Each rating performed on the site is kept in the database and can be used to calculate custom ratings on. The various options allow to adapt the score calculation to reflect the importance on the site, whether it is to support quality improvement on documentation or to rank incoming data on a feed aggregator.

- **object**, mandatory and always *(object type object-id)* in this context.
- **range**, to limit how long votes are considered. Argument is provided as a number of seconds.
- **ignore**, with *anonymous* as an argument to only consider votes from registered users.
- **keep**, to only consider one vote per visitor. Unless the option is present, all of the votes are taken into account. The option can be either *latest* or *oldest* to indicate which one to keep.
- **revote** can be specified if keep is specified. Indicates the time period required between votes. For example, users could be allowed to vote more than once per day, but only their latest vote each day would be considered, if revote is set to mul(24 3600). If the user voted yesterday as well as today, both votes will be counted.
article-info
Pulls information from an article to include in the calculation. The first argument must always resolve to 'article'. If any other value, the calculation will be skipped for the evaluated object, making the formula type-specific.

Available properties:
- rating, the static rating attached to the article
- view-count
- age-second
- age-hour
- age-day
- age-week
- age-month

Examples
(\(\text{article-info type object-id rating}\))
(\(\text{article-info (str article) 42 age-month}\))

attribute
Pulls information from the generic object attributes.

Examples
(\(\text{attribute (object type object-id)}\))
(\(\text{attribute (object (str wiki page) 14) (property tiki.proposal.accept) (default 0)}\))

tracker-field
Pulls information from the tracker item. The field value is converted to numeric value automatically. Zero is provided if the value is not found or unapplicable.

Examples
(\(\text{tracker-field (object (str trackeritem) 42) (field priority)}\))
You can pull the value of an item coming from an item link and an item dynamic list field type (not tested on item list). This imply using the permaname of the item link tracker field and the permaname of the field that contain the value (in the other tracker).

```plaintext
(value form item link item
  (tracker-field
    (object (str trackeritem) permaname_thistrackerfield)
    (field permaname_othertrackerfield)
  )
)
```

category-present
Gives 1 in score of every listed category present on the object.

```plaintext
Examples
(category-present
  (object type object-id)
  (list 3 4)
)
-> [0, 1 or 2 - Depending on how many of categories 3 or 4 are on the object]
```

Appendix
When unified search is used, recalculation can be configured to be done during re-indexing, removing the need for this script.

```php
<?php
  chdir('/path/to/tikiroot');

  require_once 'tiki-setup.php';
  require_once 'lib/rating/ratinglib.php';

  $ratinglib->refresh_all();
```

Sample and use case
Calculate date difference to see if tracker item is new or not
In this use case we compare a field that contains creation date to the actual date and if the difference is lower than 7 days (604800) the field will have the value "new" else "notnew".
Using Concat to create a reference made of month and string value from other fields

In this use case we concatenate the month as word from a date field and a value from a text field (can be a dropdown, etc) and we use to create a reference for this item. Then the result, the value, can be used for many things like populating an itemList field, filtering, searching, etc.

Filling a field with value for type and month

(\text{concat} \ \text{trackerPermanameType} \ \text{str} \ " \ | \ " \ \text{date} \ \text{str} \ F \ \text{trackerPermanameDate})

For example it will set the value of field with: "Credit | February"

Assign a label to a range of values

In this case we combine less-than and more-than in a cascade of conditions to determine what value (a label) should be saved in the field based on a numerical value from another existing field. For example we have appartments and a field with their surface and we want to group them by size (less than 80m2, between 80m2 and 120m2, etc...)

\text{If used in a search (customSearch, pluginList filter, etc) the label must be unique; Tiki search engine (tested with MySQL search) will consider characters like ",", ",", "+" (may be more) as separators and not character of the string. For example if you search for "20" both "10-20" and "20-30" will be outputted in the results.}

To add some safeties we can also test first if there is a value in the field.

Here the idea is to check if the trackerPermanamePrice contain a value (price) then to group the items within the same range of prices by giving them a label.
