

This page [needs review](#)

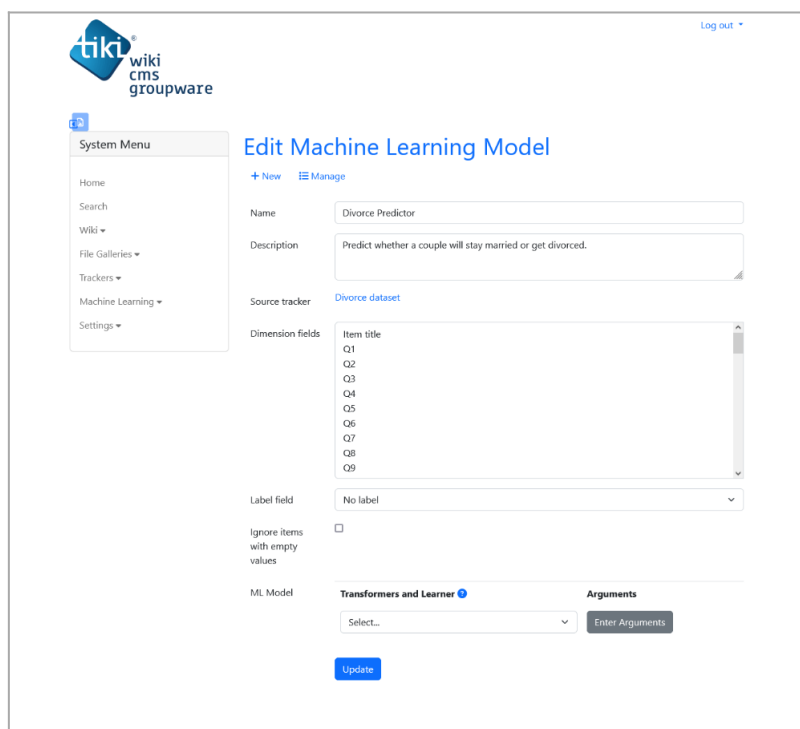

Machine Learning models are configured in accordance to the task they are to perform.

## Configuring Machine Learning Models

Configuring a model to make it ready for training involves specifying the data dimension fields, a label field if necessary, any required transformers and a learner. You can get to the model configuration page by finding the model in the Machine Learning **List Models** page, click on the model's actions button and select **Edit**.

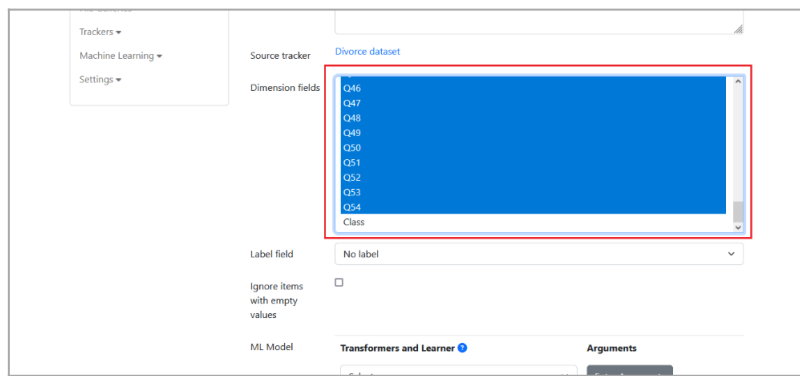

Find edit option in model's action menu

Model configuration page

## Selecting Dimension and Label Fields

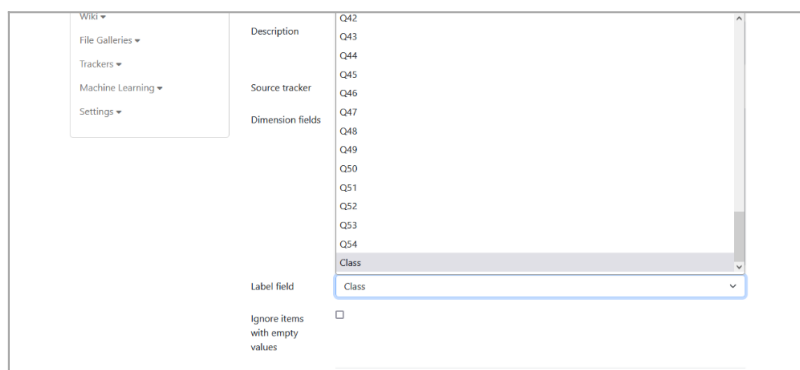

Dimension fields are chosen from a list of fields gotten from the data source tracker. These are shown in a multiselect list interface. Select a field by clicking on it. Select multiple fields by holding down the **Ctrl** keyboard key and clicking on the fields.

Select dimension fields from multi-select list

Chosen dimension fields are the data attributes that model will be trained on. Tiki will leave out all unselected fields.

The label field is the data attribute that contains the target to be predicted. A label field is required if the chosen learner is a classifier.

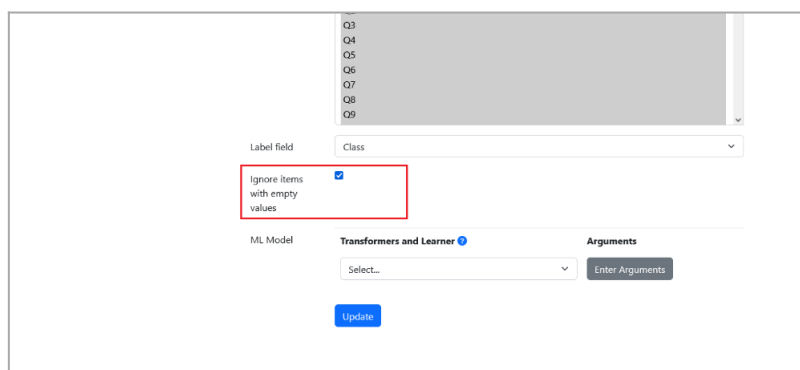

Set label field if required by learner

Some regression-based learners like [Gradient Boost](#) will also require a label field specified. In such a case, the data attribute chosen as the label field is usually expected to be of numeric type.

### Handling Empty Data Values

Before a sample is used for training, Tiki by default will replace empty numeric fields with 0. Empty categorical fields will remain as empty strings. If you do not want this behaviour, you can make Tiki to simply ignore samples with empty fields by checking the **Ignore items with empty values** option.

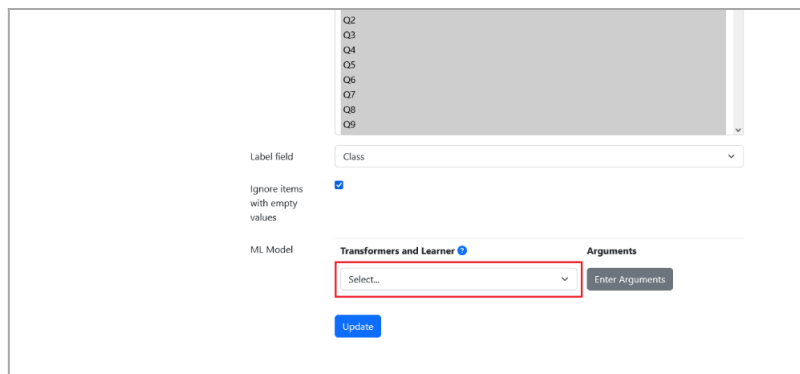

Check the box to ignore empty data values

With this option checked, Tiki will skip any item that contain empty fields during model training, and it will not be used to train the model.

### Adding Transformers and Learners

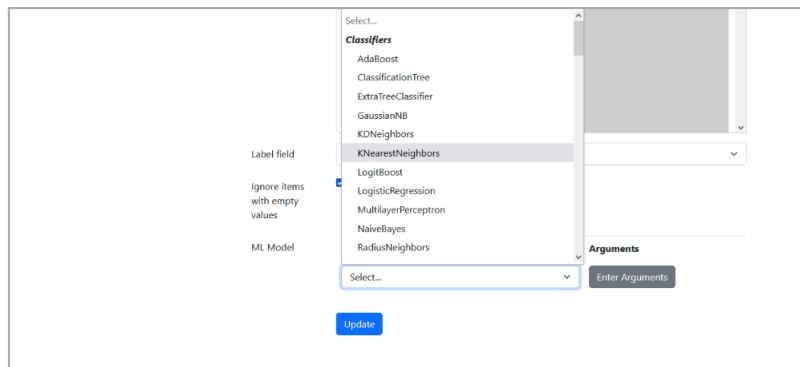

You use transformers to preprocess data before model training. A learner is a machine learning algorithm on which the machine learning model will be based. The type of transformers and learner you choose will

depend on the structure and format of the training data and the type of target that you want to predict.

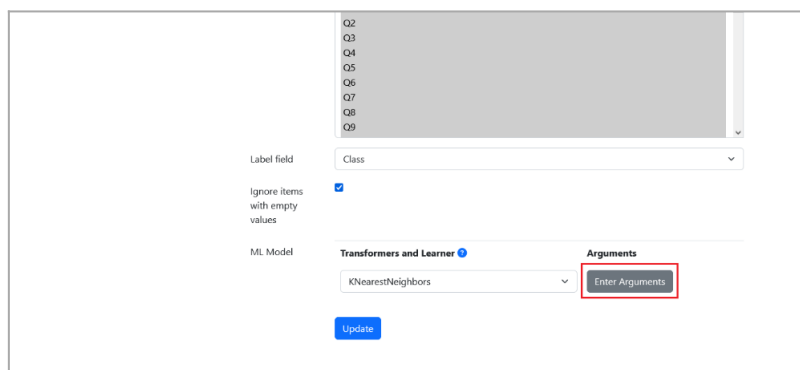

The screenshot shows a web interface for machine learning. On the left, there are labels for 'Label field' (set to 'Class'), 'Ignore items with empty values' (checked), and 'ML Model'. The 'ML Model' section has a dropdown menu labeled 'Transformers and Learner' with a red box around it. To the right of this dropdown is an 'Enter Arguments' button. Below the dropdown is an 'Update' button. On the right side of the interface, there is a list of items labeled Q2 through Q9.

Choose a transformer or learner

This screenshot shows the 'Transformers and Learner' dropdown menu open, displaying a list of classifiers. The 'KNearestNeighbors' option is highlighted. The list includes: AdaBoost, ClassificationTree, ExtraTreeClassifier, GaussianNB, KDNeighbors, KNearestNeighbors, LogitBoost, LogisticRegression, MultilayerPerceptron, NaiveBayes, and RadiusNeighbors. The 'Enter Arguments' button and 'Update' button are also visible.

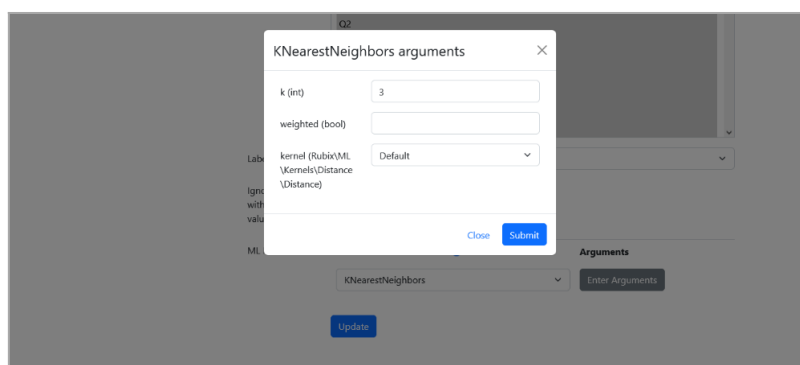

Pick a transformer or learner from the list

The screenshot shows the 'KNearestNeighbors' option now selected in the 'Transformers and Learner' dropdown. The 'Enter Arguments' button is highlighted with a red box. The 'Update' button remains visible below.

Click Enter Arguments to show popup

Add a transformer or a learner by simply selecting it from the dropdown list and clicking on **Enter Arguments** button.

The screenshot shows a modal dialog box titled 'KNearestNeighbors arguments'. It contains three input fields: 'k (int)' with the value '3', 'weighted (bool)' which is empty, and 'kernel (Rubik\ML\Kernels\Distance\Distance)' with a dropdown menu set to 'Default'. There are 'Close' and 'Submit' buttons at the bottom of the dialog. The background interface is dimmed.

Enter arguments

Learner added

A popup will be displayed for you to enter the argument values to be used internally to control the transformer or learning algorithm. Tiki will autofill any left out parameters with default values.

Fully configured

ID	Name	Description	Source
1	Divorce Predictor	Predict whether a couple will stay married or get divorced.	<a href="#">Divorce dataset</a>

Success message after configuration

You add transformers in the order in which you want the data processed and you can add as many transformers as you deem fit. As a convention, the learner should be added last and only one learner is required. Adding multiple learners might result in unexpected behaviour.

Tiki internally uses [Rubix ML](#) for its Machine Learning functionality, so only transformers and learners

available in Rubix ML are supported by Tiki.

Due to Tiki Tracker's robust nature, some data transformations might not be necessary. For example, [Numeric String Converter](#) works by converting all numeric values that have been given as categorical values to their equivalent integer and floating point types. Tiki will handle this automatically if the given values belong to a numeric field type in the source tracker. Applying the least possible number of transformers will help reduce model latency.
